

Exercises: Event Handling

- 1.** Make a form with a button (`h:commandButton`) that says “Inverse Video.” When the button is pressed, toggle between white-on-black and black-on-white. To make this work properly, you will want to do two things in your style sheet:
 - Remove all references to explicit foreground or background colors in `body`, `h1`, `th`, `legend`, etc.
 - Make two new styles (e.g., “.light” and “.dark”) that set color and background-color appropriately. If you are a bit rusty on CSS, just steal `styles.css` from my `event-handling-exercises` project, but write the Java code yourself.
- 2.** Do the same basic task, but this time use a checkbox instead of a button. Try your application in both Internet Explorer and Firefox. Make sure it works the same on both.
- 3.** Copy your form from the `properties-files` exercises. That is, create a form that collects a first name, last name, and email address and that uses a properties file for the prompts and button label. Now, make push buttons (or radio buttons) that say “English”, “Español”, and “Français” (or whatever languages your properties files support). Change the language of the page based on which entry is selected.
