

Exercises: Page Templating

1. Make a very simple template with only two overrideable regions: title and body content. Make two client pages, each of which use the same template, but both of which supply different values for the title and the body content. Hint: start simple; don't use any JSF tags, components, forms, or beans. Get it working with simple HTML before trying anything fancier.
2. Make a page template that contains the following:
 - A header that is the same in all client files.
 - A title that can change on each page.
 - Body text that is different on each page.
 - A footer that rarely changes. That is, make a default footer, but make it possible for the footer to be overridden.
3. Make several pages that use this template, but with different titles and body text. Make at least one page that overrides the footer.
4. Add an image to the template. Make the image still work, regardless of whether the page that uses the template is in WebContent or a subfolder of WebContent.
